Where the unreported pathogens are

928 wheat libraries with field coordinates, 384 localities, 35 countries. A point is drawn only where the species was detected in a study that did not report it.

Open grey points are every sampled locality, repeated in each panel, so an empty region reads as sampled-and-not-found rather than unsampled.
Point density follows sampling effort: the map locates a species, it does not measure how often it occurs. For that, see the per-country rates.
All libraries were collected from visibly diseased plants, so these are not prevalence surfaces.
