Why the rice studies are excluded before anything is counted

The red line is the 0.463 Gkmer inclusion floor; the shaded band is below it. Every one of 2,784 rice runs is excluded: 1,123 because the study sheltered, protected or did not report its disease exposure, 104 because the plants were raised in a chamber before transfer, and the remaining 1,557 on depth.
Rice is 1,636 single-end 51 nt runs, which at k=35 yield 17 k-mers per read against 116 for a 150 nt read, so the gap is wider than base counts suggest.
A log axis cannot show zero, so panel a omits 45 rice runs with effectively no bases recorded and 2 sorghum runs with no depth metadata. Panel b counts all 7,688.
